# Contradiction Memo

October 18, 2026

Team 3

Isaac Padilla

Our original business case assumed that people can sometimes have difficulty staying motivated or consistently participating in their hobbies because they are unable to quantify or visualize their progress. We want SkillUp's progress tracking to focus on seeing improvement in skill development rather than only measuring consistency or amount of effort. This matters because we want users to recognize that they are improving in a recreational activity rather than simply seeing that they are participating more often.

During our research we found that statistics and formal tracking are not what every individual is seeking. As seen in INT-01, some individuals can already recognize their progress through memory and direct feedback from people around them without needing statistics. In INT-03, one participant used a golf app that helped to track statistics, but when it came to actual technique improvement, they relied on their recordings. We are now trying to determine what tools, and information could help individuals analyze their techniques and recognize actual improvement.

INT-03 helped us understand the difference between tracking statistics and understanding technique. Statistics can show you the result of changes, but they may not explain the changes a person needs to make to improve. Understanding techniques can help individuals identify how to improve. This does not mean our original assumption is wrong but instead it shows us that our progress tracking needs to be more comprehensive. One SkillUp limitation is that we are focusing on keeping activity history and recording custom statistics to show progress instead of helping users understand what they need to improve.

Initially we did not intend to include tools for analyzing techniques directly in the app, but we found that we should make it easier for users to record their activity sessions and compare them to past performances. Part of seeing your progress is reviewing your past and current performances. Instead of relying only on statistics, individuals should be able to analyze their own activity history and evaluate how their skills have improved.
